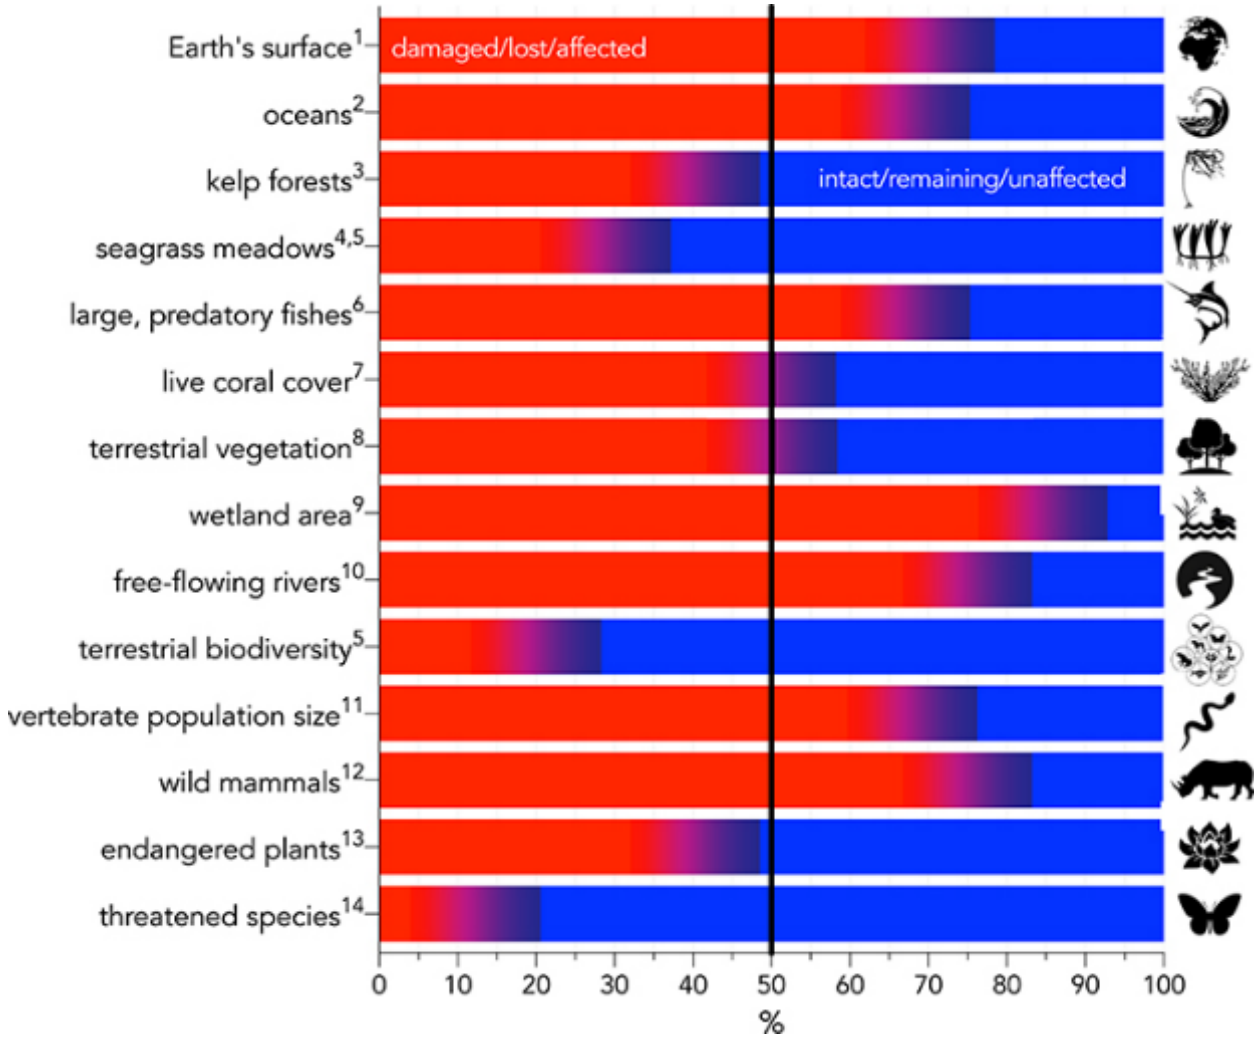
Czech Agrifood Research Center



Almost 600 plant species have been lost from the wild in the last 250 years [Humphreys A. M. et al., 2019].

> *"Ecosystems, species, wild populations, local varieties and breeds of domesticated plants and animals are shrinking, deteriorating or vanishing. The essential, interconnected web of life on Earth is getting smaller and increasingly frayed," said Prof. Settele. "This loss is a direct result of human activity and constitutes a direct threat to human well-being in all regions of the world."*

PARIS, May 2019– report from the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES)

Canine and feline blood transfusions

Despite the various blood products for dogs made available by Pet Blood Bank UK, there is currently no system available for cats in the UK. It is crucial that veterinary nurses and surgeons know how to collect blood in emergency situations and how to administer blood and blood products safely.
This article focuses on the importance of blood typing and cross matching to try and minimise potential reactions. It also highlights the criteria for appropriate canine and feline donors and how to collect blood safely.

INTRODUCTION

All farm veterinarians dread the midnight call to severe vaginal haemorrhage in the freshly calved cow. Many of us will have arrived half-dressed and breathless, only to find our patient dead or on the point of expiring (Fig. 1). Sometimes haemorrhage has been controlled, but the patient is in a state of haemorrhagic shock. Therefore, a simple, rapid and inexpensive blood transfusion technique is vital for the farm veterinarian in treating this and many other bovine conditions (Table 1).

may reduce losses sufficiently to preserve life or even make transfusion unnecessary. A severely shocked patient may be stabilised by administration of hypertonic saline while a donor can be identified. However, this effect is temporary, and after 30 minutes the crystalloid solution will have redistributed through the body and shock will once again set in.

Cattle have the most complex blood group system of domestic animals with 11 groups, but most individuals do not have antibodies against other blood group antigens unless sensitised by previous transfusion. Even where cross-matching is carried out, transfused erythrocytes only survive for 2-4 days compared to a normal cattle lifespan of 160 days. Nevertheless, this window is usually enough to allow endogenous haematopoesis to fill the deficit.

The anticoagulant of choice in bovine blood transfusions is sodium citrate, which is both cheap and readily available. Unlike heparin, it does not have

COMPLEX CRYOPRESERVATION MEDIUM FOR MAMMALIAN ERYTHROCYTES

INTRODUCTION

Successful cryopreservation of animal erythrocytes is hampered by the need for individual choice of the protocol due to species differences. The solution to this problem can be complex cryoprotective media (CCM). The aim of this work was to develop CCM that could become unified for mammalian erythrocytes.

MATERIALS AND METHODS

1. washed erythrocyte + cryopreservative medium
2. 15 min incubation
3. Freezing by immersion into liquid nitrogen (–196°C)
4. Thawing in a water bath at 40°C up to liquid phase appearance
5. Washing

Final cryoprotective concentration in cell suspension:

1. 2.5% PEO-1500 +7.5% Me_2SO
2. 5% PEO-1500 + 5% Me_2SO
3. 10% PEO-1500 +5% Me_2SO
4. 5% PEO-1500 + 5% Me_2SO + 5% 1,2-PD + 5% sucrose
5. 7.5% PEO-1500 + 5% Me_2SO + 2.5% 1,2-PD + 2.5% sucrose
6. 7.5% PEO-1500 + 7.5% Me_2SO + 2.5% 1,2-PD + 2.5% sucrose
7. 10% PEO-1500 + 5% Me_2SO + 2.5% 1,2-PD + 2.5% sucrose
8. 5% PEO-1500 + 5% Me_2SO + 5% 1,2-PD + 2.5% sucrose
9. 10% PEO-1500 +2.5% Me_2SO + 2.5% 1,2-PD +2.5% sucrose
10. 5% PEO-1500 + 5% Me_2SO + 5% 1,2-PD + 5% mannitol

CONCLUSIONS

Thus, the developed complex cryoprotective media containing polyethylene glycol 1500 (7.5%), Me2SO (5%), 1.2 propanediol (2.5%), sucrose (2.5%) is potentially unified for erythrocytes of different mammals.

PHASE BEHAVIOR OF SUCROSE-CONTAINING CRYOPROTECTIVE SOLUTIONS AT TEMPERATURES BELOW 0 °C

Introduction

Sucrose is often used both as a primary cryoprotectant and in complex cryoprotective media. In particular, sucrose is a component of many media for cryopreservation of mammalian embryos by vitrification.

Purpose

to study low-temperature phase transitions in sucrose-containing solutions of glycerol (Gl), 1,2-PD, 1,3-PD, ethylene glycol (EG), and Me_2SO.

Materials and methods

Preparing of cryoprotectant solutions

Cryoprotectant solutions (30% concentration) were prepared with Dulbecco's nutrient medium supplemented with sucrose.

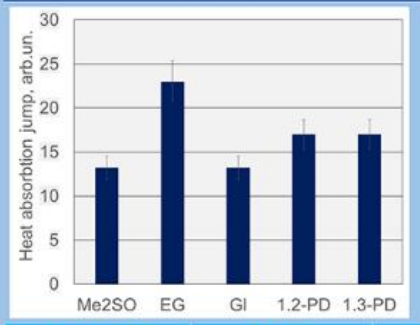
Low temperature differential scanning calorimetry (DSC)

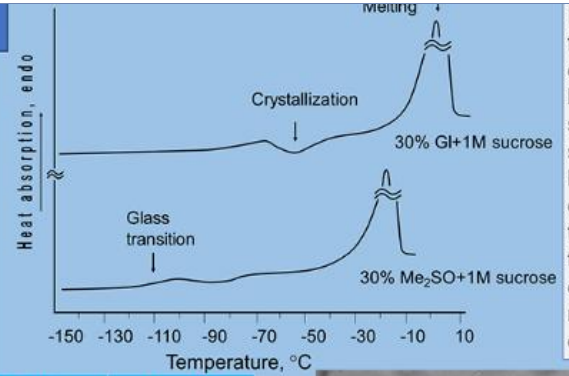
Cryoprotectant solutions (30% concentration) were prepared with Dulbecco's nutrient medium supplemented with sucrose. DSC thermograms were recorded at the heating stage (0.5 grad/min) after rapid cooling of the solutions by immersion into liquid nitrogen (200°/min). For all investigated solutions, the temperatures of phase and glass transitions were determined.

Cryopreservation of mouse embryos

2-cell and 8-cell mouse embryos in cryoprotective medium were vitrified by immersion into liquid nitrogen using plastic straws and preserved 3-7 days. Thawing was performed in water bath (38°C). To remove the cryoprotectant there was used a 10-min equilibration in 0.5M sucrose solution. Then the embryos were three times washed-out with physiological medium, transferred into CO_2 -incubator for culturing. Rate of embryo viability was estimated by their developmental capacity to the stage of extended blastocyst.

Results





Immediately after glass transition, for all investigated solutions, crystallization completed at the heating stage, which indicated a low stability of the amorphous state. In solutions of Me2SO and EG, the lowest glass transition, crystallization and melting temperatures were recorded. After the addition of sucrose no crystallization of eutectic was recorded in any of the studied cryoprotectant solutions.

Samples	T_g, °C	T_c, °C	T_m, °C
Me_2SO	-108.2±0.5	-85.3±0.5	-34.6±0.5
EG	-109.1±0.5	-86.9±0.5	-25.8±0.5
Gl	-76±0.5	-54±0.5	-11.7±0.5
1.2-PD	-72.2±0.5	-51.6±0.5	-13.9±0.5
1.3-PD	-83±0.5	-62.1±0.5	-15.1±0.5

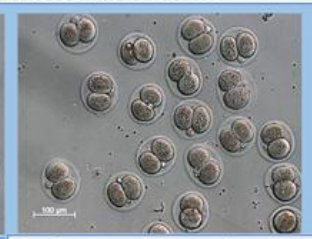
8-cell mouse embryos after vitrification using Gl-sucrose medium



2-cell mouse embryos after vitrification using EG-sucrose medium

Developmental stage	Groups	Cryopreservation medium	Number	Exposure time in cryoprotectants	Number of embryos, approaching blastocyst stage,(n)%
2-cell	control	30% EG + 0.7 M of sucrose	52[a]	–	(47) 90,4±4,1
8-cell		30% Gl + 0.7 M of sucrose			(39) 90,2±2,2
2-cell	I	30% EG + 0.7 M of sucrose	58	1,5 min	(52) 89,7±4,0
8-cell		30% Gl + 0.7 M of sucrose			(31) 84,9±4,3
2-cell	II	30% EG + 0.7 M of sucrose	53	3 min	(38) 75,5±6,3
8-cell		30% Gl + 0.7 M of sucrose			(23) 56,8±6,7[b]
2-cell	III	30% EG + 0.7 M of sucrose	74	1,5 min	(31) 55,4±7,6[b]
8-cell		30% Gl + 0.7 M of sucrose			(65) 80,2±6,2

Conclusions

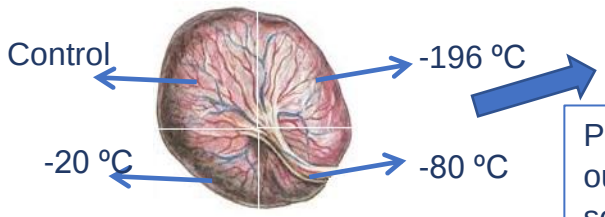
the addition of sucrose to cryoprotective solutions leads to an increase in the glass transition temperature and the disappearance of crystallization and melting of eutectic compositions.

EFFECT OF LOW TEMPERATURE PLACENTA STORAGE ON BIOLOGICAL ACTIVITY OF ITS EXTRACTS

Introduction

Low temperature storage of placenta is widely used. We have recently shown that at high cooling rates there is a small amount of liquid phase that remains uncrystallized and goes into to a glassy state at temperatures from -77°C to -81.5°C. The aim of this work was to study the effect of placental storage temperature on biological activity of its extracts.

Materials and methods



Obtaining of human placenta extracts (HPEs)

Placental fragments were washed out with 0.15 M sodiium chloride solution until the visual removal of mucus and blood; then fetal membranes (amniotic and chorion) were removed. Placenta fragments were homogenized in physiological solution (1:1, w/v) with a following incubation for 12h at 4 ºC.

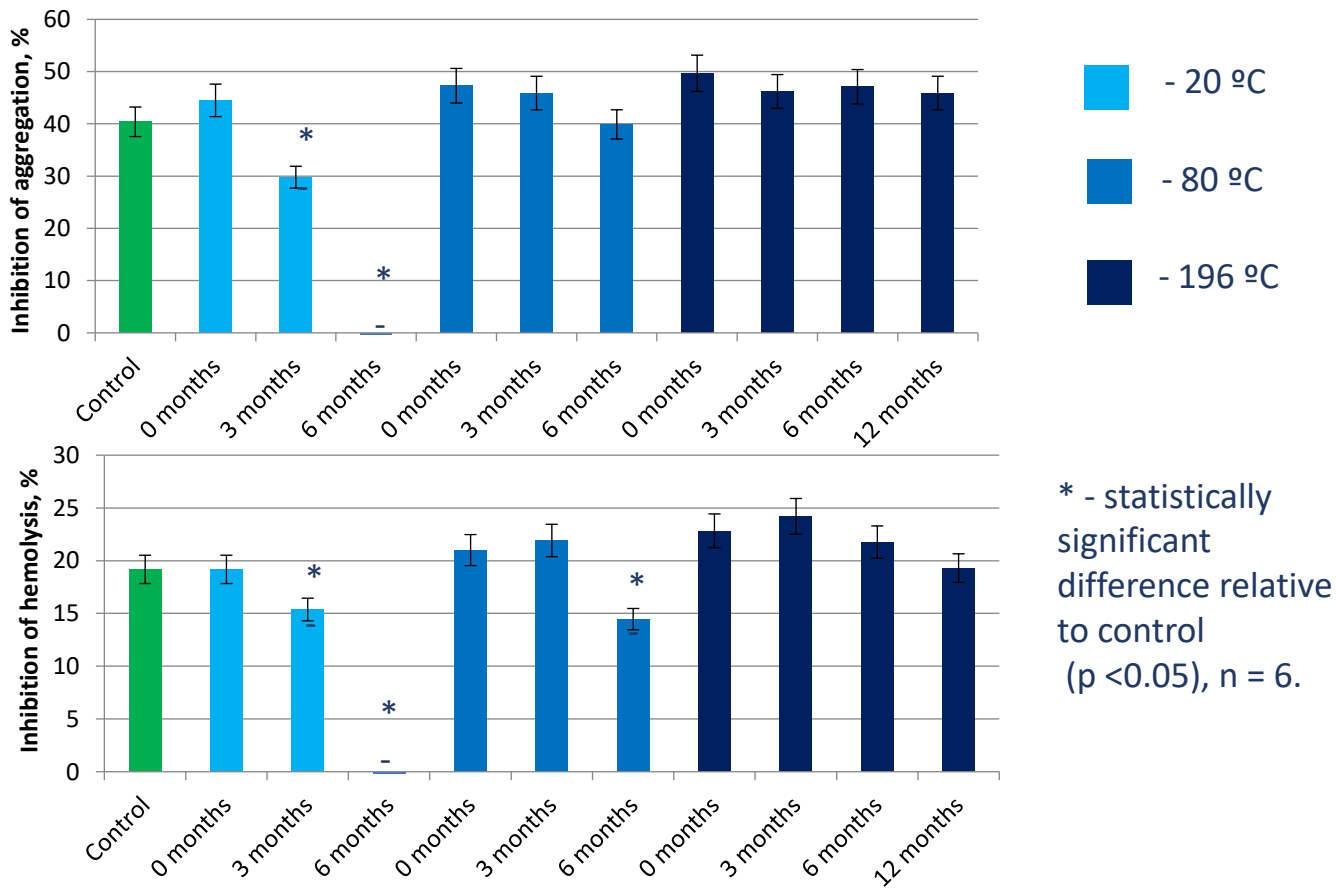
Ability of HPEs to reduce erythrocytes' thermohemolysis (20 min in thermostat at 55 ° C)

% inhibition of hemolysis = (hemolysis of control) - (hemolysis of sample)) / (hemolysis of control) * 100

Anti-aggregation activity of HPEs was determined by spectrophotometric method. Platelet-enriched plasma was incubated for 15 minutes with HPEs at +37 °C. 5'-ADP at a concentration of 10^{-5} mol/l was used as an inducer of platelet aggregation.

% inhibition of aggregation = (1- (aggregation of sample)/(aggregation of control)) * 100

Results

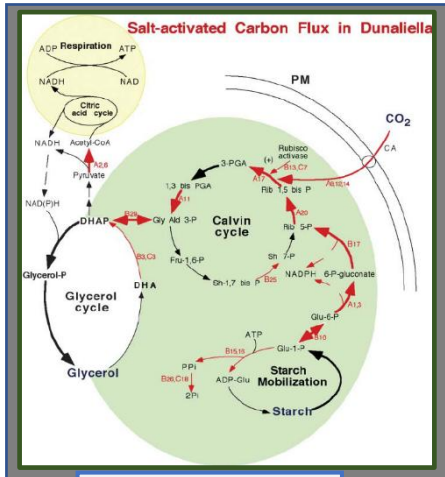


* - statistically significant difference relative to control ($p < 0.05$), n = 6.

Conclusions

Thus, placenta biological activity was maintained at -196˚C at least during 1 year, at -80°C it was kept for 6 months, and for 3 month at -20°C.

LOW TEMPERATURE PHASE TRANSITIONS IN GREEN MICROALGAE SUSPENSIONS



Liska A. et al., 2004

Introduction

Green microalgae *Dunaliella salina* is a promising source of carotene for the biotechnology industry. Cryopreservation is one of the best ways to preserve important strains of microalgae for a long time without losing their characteristic features. It is known that with a high degree of salinity, Dunaliella salina are capable of glycerol hypersynthesis. Glycerol, which accumulates in *Dunaliella salina* cells under stress, can act as a natural cryoprotectant.

Purpose

to study low-temperature phase transitions in suspensions of green microalgae *Dunaliella salina*, which were cultivated on Ramaraj media with different content of sodium chloride.

Qualitative and quantitative composition of Ramaraj growth medium

Substances	Concentration, g / l
H_3BO_3	0,00928
$CoCl_2 \cdot 6H_2O$	0,00005
$ZnCl_2$	0,00011
$MnCl_2 \cdot 4H_2O$	0,00198
Na_2MoO_4	0,00049
$NaVO_3$	0,00024
$CuCl_2 \cdot 6H_2O$	0,00005
$MgSO_4 \cdot 7H_2O$	1,23
KCl	0,2
$CaCl_2 \cdot 2H_2O$	0,044
KNO_3	0,5
KH_2PO_4	0,014
$FeCl_3 \cdot 6H_2O$	0,0005
Na_2EDTA	0,074
$NaHCO_3$	2,1
NaCl	87,7 (1,5 M)
	175,4 (3 M)
	233,76 (4 M)

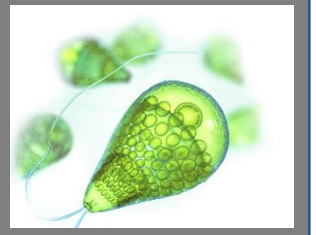
Materials and methods

Suspensions of green microalgae

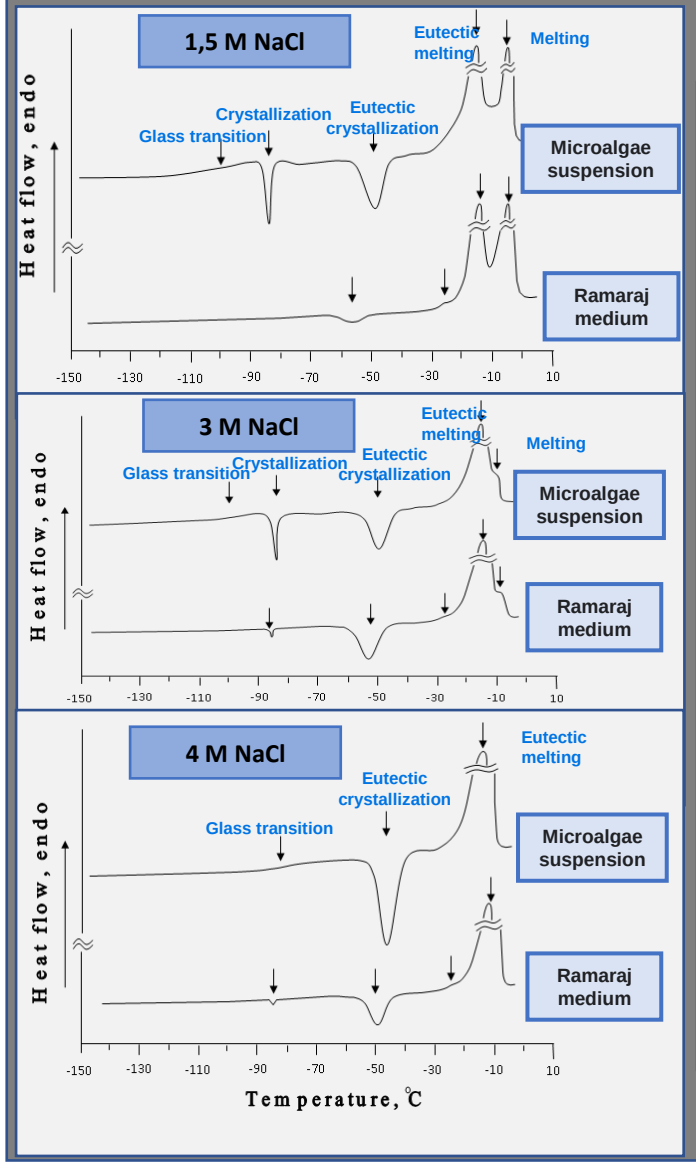
↓

Snap freezing in liquid nitrogen (~ 200°/min)

↓



Low temperature differential scanning calorimetry
Thermograms of frozen samples
were recorded while rewarming at 0.5 °/min.



Results

Glass transition was registered in microalgae suspensions that were cultured in Ramaraj medium with 1.5 M, 3M and 4M of NaCl. This indicates an effective hypersynthesis of glycerol by *Dunaliella salina* microalgae. An intense exothermic peak was recorded at the heating stage at NaCl concentrations of 1.5 M and 3M almost immediately after completion of glass transition. This indicates low stability of the amorphous state in studied cell suspensions and the need for high heating rates to prevent crystallization processes from the amorphous state. The crystallization peak was not recorded in microalgae suspension with 4M of NaCl. Two separate melting peaks were registered at 1.5 M of NaCl. They probably correspond to the melting of eutectic compositions and ice melting. An increase in NaCl concentration leads to a decrease in the melting point of ice and a lack of separation of the two melting peaks.

Many critical food and nutrition security crops cannot be conserved in perpetuity by seeds!

- Seedless crops
- Crops that do not breed true from seeds
- Crops with recalcitrant or short-lived seeds

Methods of conservation

- Field collection
- *In vitro* collection
  - Normal growth
  - Slow growth (temp↘, O_2 ↘, H_2O ↘, medium ~)
- Cryopreservation (-196°C)

Field collection = vulnerable to pests, diseases, and climate

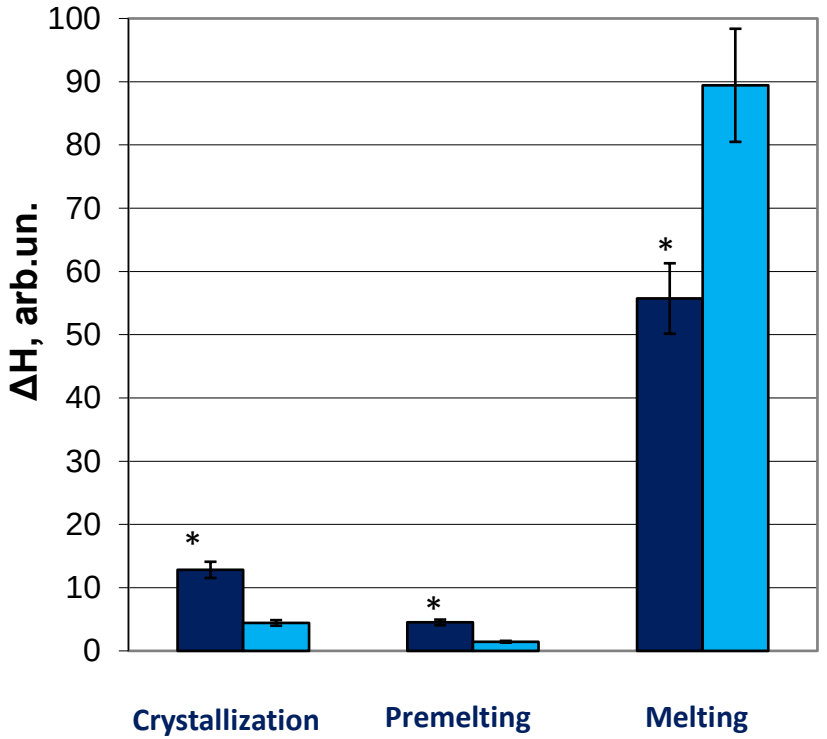
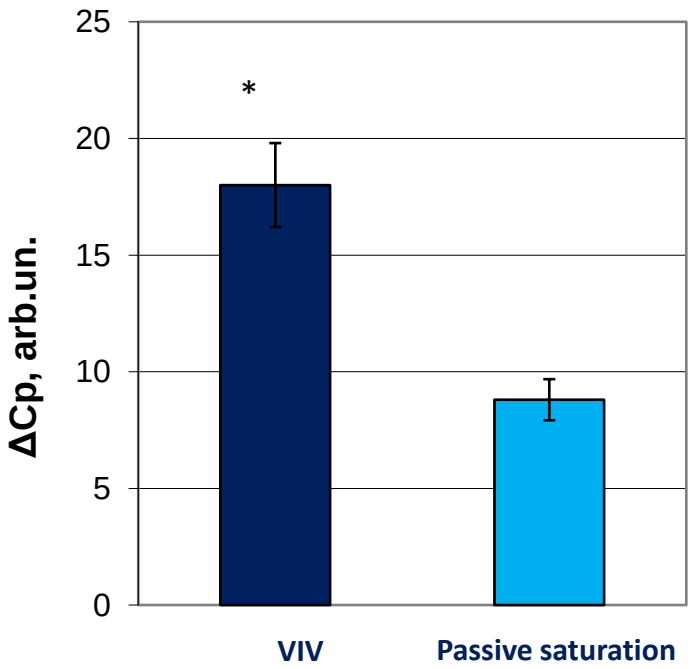
Enthalpy of phase transitions



Glass transition in grape buds



* Values are statistically different compared to the values for the passive saturation (P<0.05)

Grape dormant buds cryopreservation

Saturated buds	T_g, °C	T_c, °C	T_{pm}, °C	T_m, °C
Control	-87.9±1.6	-64.8±1.4	-37±0.5	-2.4±0.5
PVS1	-107.1±0.5*	-68.5±0.5	-37.2±0.5	-7.2±0.5*
PVS2	-115.1±0.5	-77.6±0.5	-37.1±0.5	-15.1±0.5*#
PVS3	-105±0.5*	-62.5±0.5	-36.4±0.5	-7.9±0.5*
PVS4	-107.2±0.5*	-77.4±0.5	-37.5±0.5	-9±0.5*
PVSN	-106.9±0.5	-85.2±0.5	-48.9±0.5	-4.1±0.5

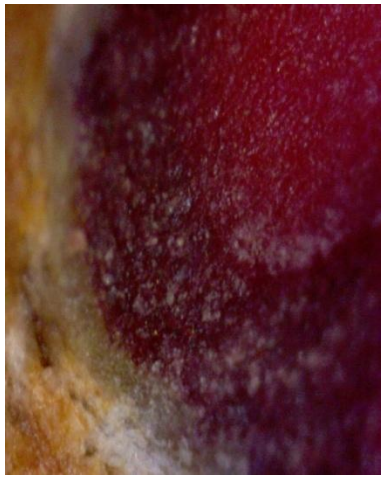
When saturated with PVSs, significant changes in heat absorption jump during glass transition, temperatures of phase transitions and their enthalpies were found. After saturation with PVS2, the temperature and enthalpy of melting were significantly lower than for PVS1, PVS3 and PVS4, which indicated a better saturation with PVS2. This may be due to the rather high content of Me_2SO.

* - statistically significant difference relative to control (p = 0.05), n = 5;
# –statistically significant difference relative to other PVS (p = 0.05), n = 5 .

Saturated buds	Δc_p	ΔH_c	ΔH_{pm}	ΔH_m
Control	9.1±1.0	0.83±0.21	0.38±0.16	174.1±29.8
PVS1	20.5±3.7*	9.22±1.15*	2.96±2.48*	68.3±9.9*
PVS2	18.0±0.9*	12.81±1.56*	4.5±0.51*#	55.72±6.34*#
PVS3	32.9±2.6*	1.98±0.56*	1.07±0.32*	116.7±17.3*
PVS4	34.8±3.9*	26.5±2.31*	0.42±0.13	73.6±11.5*
PVSN	12.3±2.1	1.33±0.17	0.79±0.13	123.5±11.5

Grape dormant buds cryopreservation

Viability of grape buds



Regrowth of grape buds

VIV enabled 60% level of grape buds' viability for Russian Concord and Riparia X Rupestris varieties and 80% level of viability for Zagadka variety after cryopreservation. Regrowth of grape buds was 30% for Russian Concord, 40% for Zagadka , 0% for Riparia X Rupestris.
There were no integral and viable grape buds while using passive saturation approach.

Dormant bud cryopreservation of Rubus idaeus L.

Olena Bobrova [a b], Jiri Zamecnik [a], Milos Faltus [a], Alois Bilavcik [a]

Conclusions

Cryopreservation of dormant buds has proven to be an effective method for preserving raspberry genetic resources. The two-step freezing process of dormant raspberry buds, following initial dehydration, achieved regeneration rate of up to 74–86 %. The highest regeneration rates were observed when the buds were dehydrated to a moisture level of 22–23 % and a water activity of 0.83–0.85. Optimal conditions for the two-step freezing process included an initial hardening temperature of −30 °C for 24 h, followed by rapid thawing after cryopreservation.

Conclusions

- Thermal characterization and analysis of water activity in twigs and buds provide important information about the water status of plant tissues, which is necessary for successful cryopreservation.
- Two isotherms during cooling are typical for apricot and raspberry tissues, however, for twig, the percentage of strongly supercooled water is many times greater than for buds.
- The moisture content of buds is higher than that of twig, therefore, the determination of the average moisture content of single-node segments for cryopreservation is incorrect and does not allow estimating the moisture content of the buds themselves.
- Crystallization in twig tissues occurs at lower temperatures and the percentage of crystallized water is lower than for buds.
- At moisture levels in plant tissues below 25-30%, the water is prone to supercool and may be in the glassy state at low temperatures. However, part of this glassy phase is metastable and can crystallize during heating.
